Our principles: Single responsibility, code documentation and clean code.

Explanation for Correct Code:

The correct code follows the three principles: single responsibility, code documentation, and clean code.

Single Responsibility: The Calculator class is responsible for mathematical operations, while `main()` handles user interaction and program flow. Each calculator method also only handles one specific operation.

Code Documentation: The code uses docstrings to explain the purpose of the class, methods, and `main()` function. The documentation is brief and avoids unnecessary comments that simply repeat the code.

Clean Code: The code uses meaningful names, simple methods, and straightforward logic. This makes the code easier to read, understand, and maintain.

Explanation for incorrect code: The incorrect code violates all of our chosen coding practice principles. Two of the functions perform two different calculations, which violates the single responsibility principle. There are no comments at all which violates the code documentation principle. This makes it hard to explain the goal of certain code segments. Lastly, the clean code principle is violated. The chosen names for the functions are vague and don't represent what the function does. The functions do too many things, and the user interface is not intuitive making it hard or confusing to use.
